ATARI PAL → SECAM BOARD.

B 10/82.

NOTES ON ATARI SECRET CONVERTER

1. Setting Up.

- 1.11 Disconnect interface ckt. from MC 1376 pin 5
- 1.12 With pin 5 of MC 1376 open, tune inductor for an oscillator frequency of 4,400 MHz.
- 1.13 Reconnect interface to pin 5.
- 1.21 Observe waveform at MC 1376 pin 5 with calibrated oscilloscope.
- 1.22 Ground TDA 3333 pin 17 to kill demodulator
- 1.23 Adjust B-Y potentiometer for 2,70V on B-Y lines
- 1.24 Adjust R-Y potentiometer for 3,25V on R-Y lines } At +12.00V supply.
- 1.31 Adjust Post-filter inductor for centre freqn of 4,286 MHz.
A possible quick method is:
 - 1.311 adjust for minimum unmodulated subcarrier on B-Y lines.
 - 1.312 reduce inductance so that R-Y subcarrier is reduced until a just noticeable rise in B-Y amplitude is obtained
- 1.32 This adjustment is fairly critical for transient response.
The above quick method appears adequate but is necessarily imperfect.
There is no straight forward method of getting it right except to optimise the transient response of a reference receiver which has been previously set up using a standard signal generator.
- 1.41 Observe waveform at collector of LUM processing input transistor.
- 1.42 Adjust trim for minimum subcarrier.

2 Remarks

2.1 Supply Voltage.

The choice of +12V is determined by a) TDA3333

b) MC1376 - frequency range is otherwise inadequate and at +5V the modulation characteristic shows a slope reversal.

c) Simplification of interface.

2.2 Temperature Effects

The interface circuit is designed to minimize temperature coefficients, hence the inclusion of three diodes.

2.3 Modulation Errors.

The most marked error is an H/2 component in the PAL signal provided by ATNR1. The colour in Secam therefore depends on the relative phase of the H/2 control signals in the TDA3333 and the re-modulator. As a consequence switching off and on again can change the colour. This can be eliminated by adding a PAL delay line to the TDA3333 to average over two lines.

2.4 Beats

Feeding PAL composite video to the LUMA processor results in beats between PAL and SECAM subcarriers. A 270p trap tuning is essential even to obtain results of doubtful acceptability. This cuts LUMA bandwidth. There remains a certain amount of SECAM noise ("spikes") due to capture of the discrimination by residues of PAL transients, also beating. The best approach is to feed clean LUMA and use 470pF trap tuning for safety.

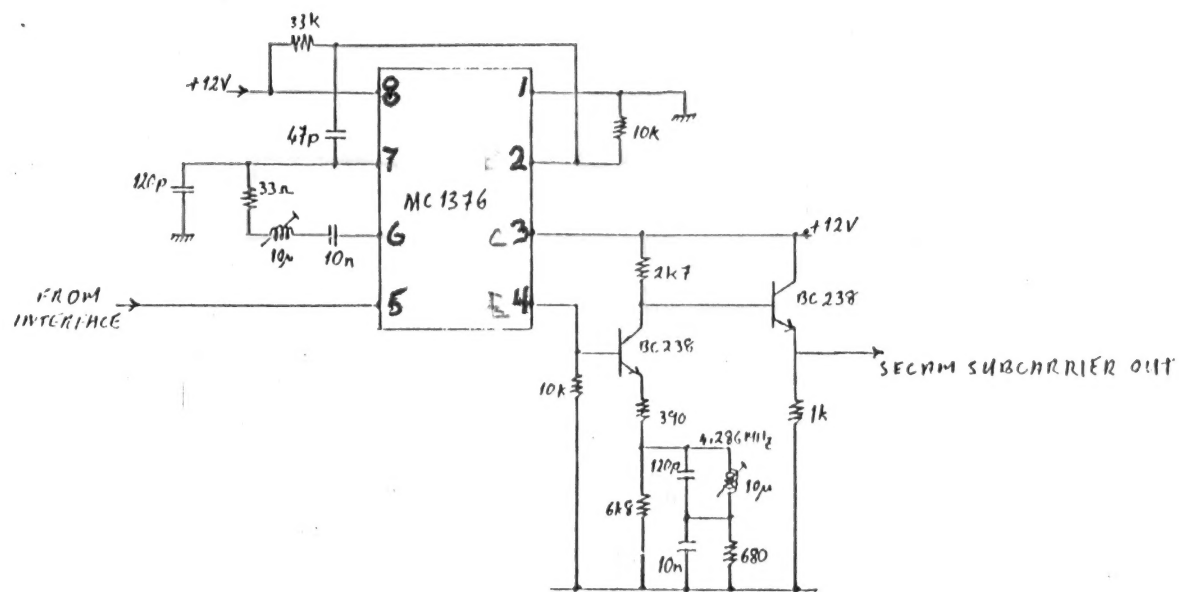

2.5 Subcarrier blanking.

As shown the system does not blank subcarrier during syncs. If this proves a problem, the pulse processor makes available Hsync and Vsync for this purpose.

Mr. Paul Fung
Consulting Engineer
Atari Inc.
2820 Orchard Pk.
San Jose, CA. 95134

Dear Paul,

Enclosed are Lambda PM83 switching regulators configured for your application. In the rush to get this product assembled a bonding error was made such that the frequency compensation pin(CMP) was not bonded to the package(another device pad was substituted). By changing loop frequency compensation we were able to approximate the performance of the first prototype board. The difference you will measure at the $V_{out}(+12)$ terminal is 5mv more RMS noise. However, the primary purpose of this test run was verification of 14 pin 'Bat-Wing' package power dissipation capability. The test board we constructed achieved 27 °C/WATT temperature rise(mounted on a 2" X 2" copper board). Since your application requires .8 Watt device power dissipation no thermal problems will be encountered when the device is mounted as shown on the test board ie. all GND pins connected to a 4 sq. inch thermal radiating area.

I have also enclosed a schematic that details the circuit modifications.

We feel that the Lambda PM83 type switching regulator will meet your application's requirements in a low cost, machine insertable package.

If you have any questions please call me.

Regards,

Paul Tomlinson
